Postfreeze Qualification Corrigendum

AGI ALPHA Consequential009 / 30 October 2026

This corrects the validation scope of the accompanying nine-page study, When More Measurements Cannot Help. The original PDF and its 95-input scientific freeze remain unchanged. Its historical 131/153 checks and the intermediate summary-only 153/170 correction retain their exact earlier source scope; none is transferred to the final operator-aware validators. The intermediate correction is preserved in history.

Configured review of public checkpoint 49838402 exposed a report-integrity defect. Both earlier validators could accept altered REPORT summary counts or completion flags while independently checked detailed plans and readouts remained correct. The reference validator could also accept forged summary claims of drift/high-noise success despite detailed records correctly requiring abstention. Exact counterexamples and original accepting receipts are preserved. No wrong numerical value was found in the actual native reports.

The summary repair reconciles counts, acquisition costs, completion flags and stress decisions with recomputed plans and readouts. A later reproduced admission gap let an unsupported retained operator, or an invalid paired-reference operator/expression, pass while detailed numerical records were correct. Final validators independently enforce the admitted operator/schema and its required semantics. Fresh native receipts and current invalid-packet rejections appear below; candidate code, cohorts and endpoints are unchanged.

A separate consumer repair binds the exact GENERATED sidecar and protocol bytes to the acceptance receipt before storage, then parses those same checked buffers. Three integration tests pass: post-receipt substitutions are refused and the unchanged valid instrument still executes all twelve memory/control arms. This consumer result is distinct from independent verifier admission. No universal program-integrity or physical-assurance claim follows.

Report	Fresh checks	Native artifact	Invalid packet
Circuit report	159/159	Accepted	Operator rejected
Reference report	176/176	Accepted	DSL rejected

The scientific and commercial conclusions are unchanged: conditional ideal-network enablement, parity with known complete methods, and no demonstrated physical calibration or after-cost discovery advantage. The nominal SIM USD 12.25 surplus and joint adverse SIM USD 87.75 loss remain authored conditional results. Qualified unrestricted simulated earnings remain zero; neither this integrity repair nor the additional reference instrument is claimed as earned-funded construction. Mission completion and live commerce remain unestablished.

Source 49838402 was downloaded as 114547736 bytes and all 7857 Git blobs checked. A fresh-environment replay completed in 8.129932 seconds using its earlier checkers. Separately, its paper builder ran without compilation using all 95 archive-aware inputs; all four generated text derivatives match the original final files byte-for-byte. The original public reading edition was actually inspected in Chrome. These historical qualifications do not qualify a later patched download or the new correction banner; each requires its own receipt.
